Conclusion

- Understanding factorisation and especially why the Number Field Sieve is the best current factoring approach.
- Understand why a more “natural ” approach using the Riemann ζ function fails. Are we doomed to bang into a wall through an *analytic* approach?
- Get some money from RSA challenges (no current income).

Fermat's Idea

A New Factoring Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with L-functions

Conclusion

Suppose we can find x, y integers with $x^2 \equiv y^2 \pmod{N}$ and $x \not\equiv \pm y \pmod{N}$. Then $1 < \gcd(x - y, N) < N$ and this can be computed quickly, giving rise to a nontrivial factor of N .

Fermat's Idea

A New Factoring Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with L-functions

Conclusion

Suppose we can find x, y integers with $x^2 \equiv y^2 \pmod{N}$ and $x \not\equiv \pm y \pmod{N}$. Then $1 < \gcd(x - y, N) < N$ and this can be computed quickly, giving rise to a nontrivial factor of N .

To find x and y , the most successful technique uses smooth numbers (divisible by “small” primes only). It is due to Morrison & Brillhart.

This idea is at the heart of the most successful factoring methods (QS and NFS), except ECM.

Running Times

A New Factoring Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with L-functions

Conclusion

ECM, QS, NFS all have subexponential running times.

Running Times

ECM, QS, NFS all have subexponential running times.

- QS: $\exp((c_1 + o(1))(\log N)^{1/2}(\log \log N)^{1/2})$
- ECM: $\exp((c_2 + o(1))(\log p)^{1/2}(\log \log p)^{1/2})$, (where p is smallest prime dividing N)
- NFS: $\exp((c_3 + o(1))(\log N)^{1/3}(\log \log N)^{2/3})$

- Much room for future improvements.

Approaching Multiplicative Functions

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

Let $\phi(n)$ be the Euler phi function. Suppose that N factors as $N = pq$, so that $\phi(N) = N - p - \frac{N}{p} + 1 = f(p)$.

Approaching Multiplicative Functions

A New Factoring Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with L-functions

Conclusion

Let $\phi(n)$ be the Euler phi function. Suppose that N factors as $N = pq$, so that $\phi(N) = N - p - \frac{N}{p} + 1 = f(p)$. Then using Newton's method, an approximation to $\phi(N)$ will yield an approximation to p , which is enough to recover it.

Approaching Multiplicative Functions

A New Factoring Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with L-functions

Conclusion

Let $\phi(n)$ be the Euler phi function. Suppose that N factors as $N = pq$, so that $\phi(N) = N - p - \frac{N}{p} + 1 = f(p)$.

Then using Newton's method, an approximation to $\phi(N)$ will yield an approximation to p , which is enough to recover it.

How do we find a good approximation to $\phi(N)$?

First Attempt with Riemann

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

Riemann zeta function is

$$\zeta(s) = \sum_{n \geq 1} \frac{1}{n^s} \quad \Re s > 1$$

It can be continued to a meromorphic function in \mathbb{C} with simple pole with residue 1 at $s = 1$. Also

$$\frac{\zeta(s-1)}{\zeta(s)} = \sum_{n \geq 1} \frac{\phi(n)}{n^s} \quad \Re s > 2$$

Isolating $\phi(N)$

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

Classical: Compute $\Phi(x) = \sum_{n < x} \phi(n)$ by

$$\Phi(x) = \frac{1}{2\pi i} \int_{3-i\infty}^{3+i\infty} \frac{\zeta(s-1)}{\zeta(s)} \frac{x^s}{s} ds$$

and move line of integration “to the left”.

Isolating $\phi(N)$

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

Classical: Compute $\Phi(x) = \sum_{n < x} \phi(n)$ by

$$\Phi(x) = \frac{1}{2\pi i} \int_{3-i\infty}^{3+i\infty} \frac{\zeta(s-1)}{\zeta(s)} \frac{x^s}{s} ds$$

and move line of integration “to the left”. Problem: we hit the Riemann zeros, spooky beings! Can we avoid them?

Second Attempt with Riemann

We now consider $\sigma(N) = N + 1 + p + q$. As before, a close approximation to $\sigma(N)$ will reveal p . Here

$$\zeta(s)\zeta(s-1) = \sum_{n \geq 1} \frac{\sigma(n)}{n^s} \quad \Re s > 2$$

and hence if $S(x) = \sum_{n < x} \sigma(n)$ we get

$$S(x) = \frac{1}{2\pi i} \int_{3-i\infty}^{3+i\infty} \zeta(s-1)\zeta(s) \frac{x^s}{s} ds$$

Second Attempt with Riemann

We now consider $\sigma(N) = N + 1 + p + q$. As before, a close approximation to $\sigma(N)$ will reveal p . Here

$$\zeta(s)\zeta(s-1) = \sum_{n \geq 1} \frac{\sigma(n)}{n^s} \quad \Re s > 2$$

and hence if $S(x) = \sum_{n < x} \sigma(n)$ we get

$$S(x) = \frac{1}{2\pi i} \int_{3-i\infty}^{3+i\infty} \zeta(s-1)\zeta(s) \frac{x^s}{s} ds$$

Problem: $|\zeta(s)| \approx |s|^{(1-\Re s)/2}$ as $|\Im s| \rightarrow \infty$ so cannot move the line of integration far enough to the left (to $\Re s \leq 0$)

The Mellin Transform Approach

A New Factoring Algorithm

Francesco Sica

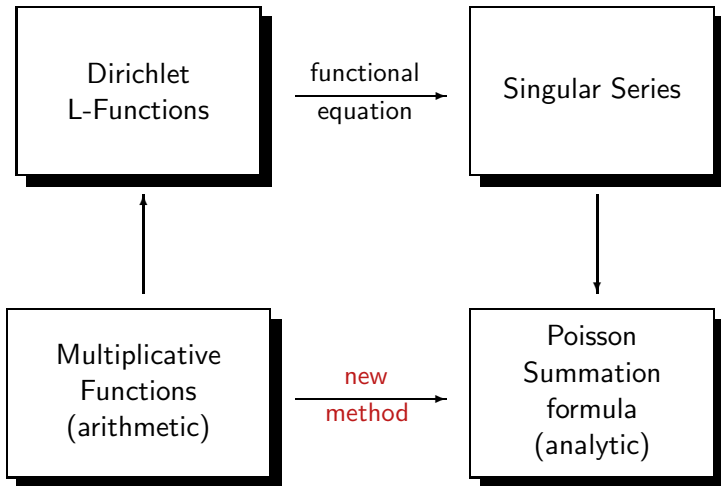

Outline

Introduction

Heuristics

Factoring with L-functions

Conclusion

Dirichlet L-functions

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

Let ℓ be prime and $\chi: (\mathbb{Z}/\ell)^* \rightarrow \mathbb{C}^*$ be a homomorphism, called Dirichlet character modulo ℓ . We define $\chi(n) = 0$ if ℓ divides $n \in \mathbb{Z}$. The Dirichlet L-function associated to χ is

$$L(s, \chi) = \sum_{n=1}^{\infty} \frac{\chi(n)}{n^s}, \quad \Re s > 1$$

Dirichlet L-functions

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

Let ℓ be prime and $\chi: (\mathbb{Z}/\ell)^* \rightarrow \mathbb{C}^*$ be a homomorphism, called Dirichlet character modulo ℓ . We define $\chi(n) = 0$ if ℓ divides $n \in \mathbb{Z}$. The Dirichlet L-function associated to χ is

$$L(s, \chi) = \sum_{n=1}^{\infty} \frac{\chi(n)}{n^s}, \quad \Re s > 1$$

It is an entire function if χ is not the trivial character, as we will henceforth suppose.

Dirichlet L-functions (cont'd)

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

We let $r \geq 2$ and $\beta_m \in \mathbb{C}$ “fixed”. Define

$$\sigma_r(n) = \sum_{d_1 d_2 \cdots d_{r-1} | n} d_1^{\beta_1} d_2^{\beta_2} \cdots d_{r-1}^{\beta_{r-1}}$$

Then

$$L(s, \chi) L(s - \beta_1, \chi) \cdots L(s - \beta_{r-1}, \chi) = \sum_{n=1}^{\infty} \frac{\sigma_r(n) \chi(n)}{n^s}$$

Mellin Transform

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

We let $\nu \in \mathbb{C}$ with $\Re \nu > 1$. Define

$$f_\nu(t) = \begin{cases} (1-t)^{\nu-1} & 0 \leq t \leq 1 \\ 0 & t \geq 1 \end{cases}$$

The Mellin transform of f_ν is

$$\frac{\Gamma(\nu)\Gamma(s)}{\Gamma(\nu+s)} = \int_0^\infty f_\nu(t)t^{s-1} dt$$

Inverse Mellin Transform

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

We have

$$\begin{aligned} \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} L(s, \chi) L(s-\beta_1, \chi) \cdots L(s-\beta_{r-1}, \chi) \frac{\Gamma(\nu)\Gamma(s)}{\Gamma(\nu+s)} x^s ds \\ = \sum_{n \leq x} \sigma_r(n) \chi(n) f_\nu\left(\frac{n}{x}\right) \end{aligned}$$

Call the right-hand side

$$F(\nu) = \sum_{n \leq x} \sigma_r(n) \chi(n) \left(1 - \frac{n}{x}\right)^{\nu-1}$$

Isolating p dividing N

We estimate

$$F^{(k)}(\nu) = \sum_{n \leq x} \sigma_r(n) \chi(n) \left(1 - \frac{n}{x}\right)^{\nu-1} \log^k \left(1 - \frac{n}{x}\right)$$

If $x = N + \frac{1}{N^2}$ we get

Isolating p dividing N

We estimate

$$F^{(k)}(\nu) = \sum_{n \leq x} \sigma_r(n) \chi(n) \left(1 - \frac{n}{x}\right)^{\nu-1} \log^k \left(1 - \frac{n}{x}\right)$$

If $x = N + \frac{1}{N^2}$ we get

$$F^{(k)}(\nu) = (-3 \log N)^k \sigma_r(N) \chi(N) N^{-3(\nu-1)} + O(N^3 (2 \log N)^{k+r})$$

Isolating p dividing N

We estimate

$$F^{(k)}(\nu) = \sum_{n \leq x} \sigma_r(n) \chi(n) \left(1 - \frac{n}{x}\right)^{\nu-1} \log^k \left(1 - \frac{n}{x}\right)$$

If $x = N + \frac{1}{N^2}$ we get

$$F^{(k)}(\nu) = (-3 \log N)^k \sigma_r(N) \chi(N) N^{-3(\nu-1)} + O(N^3 (2 \log N)^{k+r})$$

Choosing $k > c_1 r \log N$ and supposing we can compute $F^{(k)}(\nu)$ with good precision we get a value for $\sigma_r(N)$ up to an error $O(N^{-c_2})$, where $c_2 \rightarrow \infty$ as $c_1 \rightarrow \infty$. If $N = pq$, then as before this is sufficient to obtain p .

The Functional Equation

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

The Dirichlet L-function of a primitive character χ of modulus $\ell > 1$ is an entire function satisfying the functional equation (given here in asymmetric form)

$$L(s, \chi) = \frac{1}{2\pi i} \left(\frac{2\pi}{\ell} \right)^s \tau(\chi) \Gamma(1-s) L(1-s, \bar{\chi}) \cdot \left(e^{i\pi s/2} - \chi(-1) e^{-i\pi s/2} \right)$$

where $\tau(\chi)$ is the Gauss sum

$$\tau(\chi) = \sum_{m=1}^{\ell} \chi(m) \exp(2\pi im/\ell)$$

New Identities

Moving the line of integration to the left and using the functional equation shows

$$F(\nu) \approx R + \frac{\tau(\chi)^r \left(\frac{2\pi i}{\ell}\right)^{r-\beta_1-\dots-\beta_{r-1}} \Gamma(\nu)}{(2\pi i)^{r+1}} x(\cos \pi\nu - \sin \pi\nu) \\ \times \int_{(1+1/r)} \left\{ \left(\frac{2\pi i}{\ell}\right)^r x \right\}^{-s} \Gamma(s-\nu)\Gamma(s+\beta_1)\cdots\Gamma(s+\beta_{r-1}) \\ L(s, \bar{\chi})L(s+\beta_1, \bar{\chi})\cdots L(s+\beta_{r-1}, \bar{\chi}) ds$$

where R is some residue, independent of x and ν . In view of the previous expression, it is appropriate to choose $\ell \approx x^{1/r}$ so that the integral **does not** depend on x (hence N).

The Singular Series

A New
Factoring
Algorithm

Francesco Sica

Outline

Introduction

Heuristics

Factoring with
L-functions

Conclusion

Using the multiplication theorem

$$\Gamma(s)\Gamma\left(s + \frac{1}{r}\right)\Gamma\left(s + \frac{2}{r}\right)\cdots\Gamma\left(s + \frac{r-1}{r}\right) \\ = (2\pi)^{(r-1)/2}r^{1/2-rs}\Gamma(rs)$$

we arrive at evaluating terms for $F^{(k)}(\nu)$ which consist of derivatives of $\Gamma(\nu)(\cos \pi\nu - \sin \pi\nu)$ times the following series

$$\frac{1}{\tau(\chi)} \sum_{m=1}^{\ell} \chi(m) \sum_{d_1, \dots, d_r \geq 1} \frac{d_1^{-\beta_1} d_2^{-\beta_2} \cdots d_{r-1}^{-\beta_{r-1}} \log^j(d_1 \cdots d_r)}{(d_1 \cdots d_r)^{\frac{1}{2r} - \frac{\beta_1 + \cdots + \beta_{r-1} - \nu}{r}}} \\ \cdot e^{2\pi i \left(\frac{m}{\ell} d_1 \cdots d_r + (d_1 \cdots d_r)^{1/r} \right)}$$

Computing the Singular Series

The singular series can be written as

$$S_j = \sum_{d_1, \dots, d_r \geq 1} \frac{\log^j d_r}{d_1^{a_1} d_2^{a_2} \dots d_r^{a_r}} e^{2\pi i(\beta d_1 \dots d_r + \gamma (d_1 \dots d_r)^{1/r})}$$

Approximate the singular series as

$$\sum_{(d_1, \dots, d_r) \in \mathbb{Z}^r} f(d_1, \dots, d_r) = \sum_{(\delta_1, \dots, \delta_r) \in \mathbb{Z}^r} \hat{f}(\delta_1, \dots, \delta_r)$$

by Poisson summation. Here f is a $C_c^\infty(\mathbb{R}^r)$ function interpolating the summands of the singular series so that its Fourier transform \hat{f} is decreasing super-polynomially. We therefore need to compute only $O(N^\epsilon)$ terms with precision $O(N^{-c})$, which should be possible in polynomial time.
